Field of the Invention The invention relates to a method for holding substrates during processing, a holder therefor, and an apparatus for and a method of providing a substrate with a photoresist layer. 2. Description of the Related Art During semiconductor fabrication of device features on a wafer, the wafer is typically processed by treating certain portions or areas of the wafer surface. This treatment includes processes such as etching, deposition, ion implantation, and other semiconductor fabrication steps. During the treatment of the wafer, a wafer support and a holder (also known as a chuck) are used

to hold the wafer for the duration of the treatment. The particular deposition process or treatment is typically done in a processing chamber, which may be a normal-wafer processing chamber or a batch-processing chamber. After the treatment, the wafer is usually rinsed and then transported to the next processing step. The holder may include an electrostatic chuck or an air chuck. An electrostatic chuck (ESC) generates an electrostatic force to hold an object against the chuck. In the case of the air chuck, air pressure is used to generate an air bearing to hold an object against the chuck. In both cases, the wafer is placed on the surface of the holder. The problem with conventional process chambers is that they are relatively large and have a low density of process chambers. To increase the number of process chambers, one approach has been to include two or more independently controllable process chambers in a chamber housing, to form a multi-chamber process chamber. However, this type of multi-chamber process chamber is not very practical. Another approach is to include a separate process chamber dedicated to each type of process. For example, one chamber may be dedicated for etching, while another may be dedicated for implantation. Unfortunately, this approach is very inefficient, since the dedicated process chambers have unused capacity. Additionally, this approach requires substantial investment in hardware such as a control robot for transporting substrates between the process chambers. Yet another approach is to use an X-Y transport system for transportation of a wafer between the process chambers. However, this approach is also not very practical, because it requires a long distance between the process chambers. This solution also requires expensive hardware for transportation such as transport arms, valves, a system controller, etc. Moreover, the w
